ABSTRACT

Related U.S. Application Data

This invention teaches to the details of an interference suppressing receiver for suppressing intra-cell and inter-cell interference in coded, multiple-access, spread spectrum transmissions that propagate through frequency selective communication channels to a multiplicity of receive antennas. The receiver is designed or adapted through the repeated use of symbol-estimate weighting, subtractive suppression with a stabilizing step-size, and mixed-decision symbol estimates. Receiver embodiments may be designed, adapted, and implemented explicitly in software or programmed hardware, or implicitly in standard RAKE-based hardware either within the RAKE (i.e., at the finger level) or outside the RAKE (i.e., at the user or sub channel symbol level). Embodiments may be employed in user equipment on the forward link or in a base station on the reverse link. It may be adapted to general signal processing applications where a signal is to be extracted from interference.

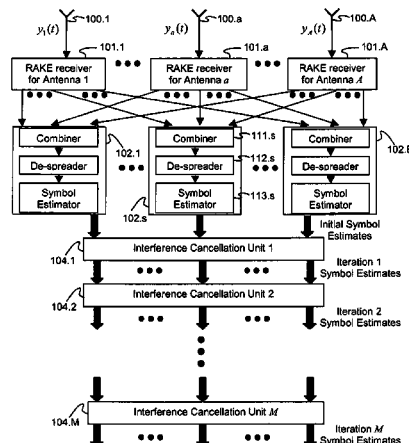

(63) Continuation of application No. 14/520,626, filed on Oct. 22, 2014, now Pat. No. 9,172,456, which is a

ITERATIVE INTERFERENCE SUPPRESSOR FOR WIRELESS MULTIPLE-ACCESS SYSTEMS WITH MULTIPLE RECEIVE ANTENNAS

CROSS-REFERENCE TO RELATED APPLICATIONS

This application is a continuation of U.S. patent application Ser. No. 14/520,626, entitled "Iterative Interference Suppressor for Wireless Multiple-Access Systems with Multiple Receive Antennas," filed Oct. 22, 2014, which is a continuation of U.S. patent application Ser. No. 13/896,952, entitled "Iterative Interference Suppressor for Wireless Multiple-Access Systems with Multiple Receive Antennas," filed May 17, 2013, now U.S. Pat. No. 8,879,658, which is a continuation of U.S. patent application Ser. No. 13/372,483, entitled "Iterative Interference Suppressor for Wireless Multiple-Access Systems with Multiple Receive Antennas," filed Feb. 13, 2012, now U.S. Pat. No. 8,446,975, which is a continuation of U.S. patent application Ser. No. 12/916,389, entitled "Iterative Interference Canceller for Wireless Multiple-Access Systems with Multiple Receive Antennas," filed Oct. 29, 2010, now U.S. Pat. No. 8,121,176, which is a continuation of U.S. patent application Ser. No. 11/491,674, entitled "An Iterative Interference Canceller for Wireless Multiple-Access Systems with Multiple Receive Antennas," filed Jul. 24, 2006, now U.S. Pat. No. 7,826,516[M], which (1) is a Continuation in Part of U.S. patent application Ser. No. 11/451,932, filed Jun. 13, 2006, and entitled "Iterative Interference Cancellation Using Mixed Feedback Weights and Stabilizing Step Sizes," now U.S. Pat. No. 7,711,075 and (2) claims priority to U.S. Patent Application Ser. No. 60/736,204, filed Nov. 15, 2005, and entitled "Iterative Interference Cancellation Using Mixed Feedback Weights and Stabilizing Step Sizes," which incorporates by reference (a) U.S. patent application Ser. The entirety of each of the foregoing patents, published patent applications and patent applications is incorporated by reference herein in its entirety.

BACKGROUND

1. Field of the Invention

The present invention relates generally to suppression of intra-channel and inter-channel interference in coded spread spectrum wireless communication systems with multiple receive antennas. More specifically, the invention takes advantage of the receive diversity afforded by multiple receive antennas in combination with multiple uses of an interference-suppression unit consisting of symbol-estimate weighting, subtractive suppression with a stabilizing step-size, and a mixed-decision symbol estimator.

2. Discussion of the Related Art

In an exemplary wireless multiple-access system, a communication resource is divided into code-space sub channels allocated to different users. A plurality of sub channel signals received by a wireless terminal (e.g., a subscriber unit or a

base station) may correspond to different users and/or different sub channels allocated to a particular user.

If a single transmitter broadcasts different messages to different receivers, such as a base station in a wireless communication system serving a plurality of mobile terminals, the channel resource is subdivided in order to distinguish between messages intended for each mobile. Thus, each mobile terminal, by knowing its allocated sub channel(s), may decode messages intended for it from the superposition of received signals. Similarly, a base station typically separates signals it receives into sub channels in order to differentiate between users.

In a multi path environment, received signals are superpositions of time-delayed and complex-scaled versions of the transmitted signals. Multi path can cause several types of interference. Intra-channel interference occurs when the multi path time-spreading causes sub channels to leak into other sub channels. For example, forward-link sub channels that are orthogonal at the transmitter may not be orthogonal at the receiver. When multiple base stations (or sectors or cells) are active, inter-channel interference may result from unwanted signals received from other base stations. These types of interference can degrade communications by causing a receiver to incorrectly decode received transmissions, thus increasing a receiver's error floor. Interference may degrade communications in other ways. For example, interference may diminish the capacity of a communication system, decrease the region of coverage, and/or decrease maximum data rates. For these reasons, a reduction in interference can improve reception of selected signals while addressing the aforementioned limitations due to interference. Multiple receive antennas enable the receiver to process more information, allowing greater interference-reduction than can be accomplished with a single receive antenna.

In code division multiple access (such as used in CDMA 2000, WCDMA, EV-DO (in conjunction with time-division multiple access), and related standards), a set of symbols is sent across a common time-frequency slot of the physical channel and separated by the use of a set of distinct code waveforms, which are usually chosen to be orthogonal (or pseudo-orthogonal for reverse-link transmissions). The code waveforms typically vary in time, with variations introduced by a pseudo-random spreading code (PN sequence). The wireless transmission medium is characterized by a time-varying multi path profile that causes multiple time-delayed replicas of the transmitted waveform to be received, each replica having a distinct amplitude and phase due to path loss, absorption, and other propagation effects. As a result, the received code set is no longer orthogonal. Rather, it suffers from intra-channel interference within a base station and inter-channel interference arising from transmissions in adjacent cells.

SUMMARY OF THE INVENTION

In view of the foregoing background, embodiments of the present invention may provide a generalized interference-suppressing receiver for suppressing intra-channel and inter-channel interference in multiple-access coded-waveform transmissions that propagate through frequency-selective communication channels and are received by a plurality of receive antennas. Receiver embodiments may be designed, adapted, and implemented explicitly in software or programmed hardware, or implicitly in standard RAKE-based hardware. Embodiments may be employed in user equipment on the downlink or in a base station on the uplink.

An interference-suppression system configured for suppressing at least one of inter-cell and intra-cell interference in multiple-access communication signals received from a plurality of antennas comprises a front-end processing means coupled to an iterative interference-suppression means.

A front-end processing means is configured for generating initial symbol estimates to be coupled to an iterative interference-suppression means. The front-end processing means may include, by way of example, but without limitation, a combiner configured for combining received signals from each of a plurality of transmission sources across a plurality of antennas for producing combined signals, a despreader configured for resolving the combined signals onto a signal basis for the plurality of transmission sources to produce soft symbol estimates from the plurality of transmission sources, and a symbol estimator configured for performing a mixed decision on each of the soft symbol estimates to generate the initial symbol estimates.

In one embodiment, the front-end processing means may further comprise a synthesizer configured for synthesizing estimated Rake finger signals for each antenna that would be received if weighted symbol decisions were employed at the plurality of transmission sources, and a subtraction module configured for performing per-antenna subtraction of a sum of synthesized Rake finger signals from that antenna's received signal to produce an error signal.

In another embodiment, the front-end processing means may further comprise a despreader configured for resolving each of a plurality of error signals corresponding to each of a plurality of antennas onto a signal basis for the plurality of transmission sources for producing a plurality of resolved error signals, a first combiner configured for combining the resolved error signals across antennas for producing a combined signal, a stabilizing step-size module configured to scale the combined signal by a stabilizing step size for producing a scaled signal, and a second combiner configured for combining the combined signal with a weighted input vector.

An iterative interference-suppression means may include, by way of example, but without limitation, a sequence of interference-suppression units. In one embodiment, each interference-suppression unit is configured for processing signals received by each of the plurality of antennas, whereby constituent signals for each of a plurality of antennas are added back to corresponding scaled error signals to produce error signals for a plurality of transmission sources, followed by resolving the error signals for the plurality of transmission sources across the plurality of antennas onto a signal basis for the plurality of transmission sources.

In one embodiment, each interference-suppression unit may comprise a soft-weighting module configured to apply weights to a plurality of input symbol decisions to produce weighted symbol decisions, a synthesizer corresponding to each antenna of the plurality of antennas and configured for synthesizing constituent signals, a subtractive suppressor configured to perform a per-antenna subtraction of the synthesized signal from the received signal to produce a plurality of per-antenna error signals, a stabilizing step size module configured for scaling the plurality of antenna error signals by a stabilizing step size for producing a plurality of scaled error signals, a combiner configured for combining each of the constituent signals with its corresponding scaled error signal to produce a plurality of interference-suppressed constituents, a resolving module configured for resolving each of the interference-suppressed constituent signals onto a signal basis for a plurality of transmit sources to produce the interference-suppressed input symbol decisions, and a mixed-

decision module configured for processing the interference-suppressed symbol decisions to produce the updated symbol decisions.

Embodiments of the invention may be employed in any receiver configured to support the standard offered by the 3rd-Generation Partnership Project 2 (3GPP2) consortium and embodied in a set of documents, including "TR-45.5 Physical Layer Standard for cdma2000 Spread Spectrum Systems," "C.S0005-A Upper Layer (Layer 3) Signaling Standard for cdma2000 Spread Spectrum Systems," and "C.S0024 CDMA2000 High Rate Packet Data Air Interface Specification" (i.e., the CDMA2000 standard).

Receivers and suppression systems described herein may be employed in subscriber-side devices (e.g., cellular handsets, wireless modems, and consumer premises equipment) and/or server-side devices (e.g., cellular base stations, wireless access points, wireless routers, wireless relays, and repeaters). Chipsets for subscriber-side and/or server-side devices may be configured to perform at least some of the receiver and/or suppression functionality of the embodiments described herein.

Various functional elements, separately or in combination as depicted in the figures, may take the form of a microprocessor, digital signal processor, application specific integrated circuit, field programmable gate array, or other logic circuitry programmed or otherwise configured to operate as described herein. Accordingly, embodiments may take the form of programmable features executed by a common processor or a discrete hardware unit.

These and other embodiments of the invention are described with respect to the figures and the following description of the preferred embodiments.

BRIEF DESCRIPTION OF THE DRAWINGS

Embodiments according to the present invention are understood with reference to the following figures.

FIG. 1 is a general schematic illustrating an iterative interference suppressor for multiple receive antennas.

FIG. 2 is a block diagram illustrating a per-antenna front-end RAKE and combiner.

FIG. 3 is a block diagram illustrating a per base-station front-end combiner configured for combining like base-station signals across antennas, a de-spreading module, and an initial symbol decision module.

FIG. 4 is a general schematic of an ICU configured to process signals from multiple receive antennas.

FIG. 5a is a per-antenna block diagram illustrating part of an interference-suppression unit that synthesizes constituent finger signals.

FIG. 5b is a per-antenna block diagram illustrating part of an interference-suppression unit that synthesizes constituent sub channel signals.

FIG. 6 is a block diagram of a subtractive suppressor in which suppression is performed prior to signal despreading.

FIG. 7a is a block diagram illustrating per-antenna RAKE processing and combining on interference-suppressed finger signals.

FIG. 7b is a block diagram illustrating per-antenna RAKE processing and combining on interference-suppressed sub channel constituent signals.

FIG. 8 is a block diagram illustrating antenna combining, de-spreading, and symbol estimation in an ICU.

FIG. 9a is a block diagram illustrating an ICU wherein subtractive suppression is performed after signal de-spreading.

FIG. 9b shows an alternative embodiment of an ICU configured for performing subtractive suppression after signal de-spreading.

FIG. 9c shows another embodiment of an ICU.

FIG. 10 is a block diagram of an ICU configured for an explicit implementation.

FIG. 11a is a block diagram illustrating a method for evaluating a stabilizing step size implicitly in hardware.

FIG. 11b is a block diagram depicting calculation of a difference signal in accordance with an embodiment of the present invention.

FIG. 11c is a block diagram depicting implicit evaluation of step size in accordance with an embodiment of the present invention.

Various functional elements or steps, separately or in combination, depicted in the figures may take the form of a micro-processor, digital signal processor, application specific integrated circuit, field programmable gate array, or other logic circuitry programmed or otherwise configured to operate as described herein. Accordingly, embodiments may take the form of programmable features executed by a common processor or discrete hardware unit.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

The present invention will now be described more fully hereinafter with reference to the accompanying drawings, in which preferred embodiments of the invention are shown. This invention may, however, be embodied in many different forms and should not be construed as limited to the embodiments set forth herein. Rather, these embodiments are provided so that this disclosure will be thorough and complete, and will fully convey the scope of the invention to those skilled in the art.

The following formula represents an analog baseband signal received from multiple base stations by antenna a of a receiver,

$$y_a(t) = \sum_{s=1}^B \sum_{l=1}^{L_{a,s}} \alpha_{a,s,l} \sum_{k=1}^{K_s} b_{s,k} u_{s,k}(t - \tau_{a,s,l}) + w_a(t), t \in (0, T), \quad \text{Equation 1}$$

with the following definitions

a represents an a^{th} antenna of a mobile and ranges from 1 to A;

(0, T) is a symbol interval;

B is a number of modeled base stations, which are indexed by subscript s, which ranges from 1 to B. The term "base station" may be used herein to convey cells or sectors;

$L_{a,s}$ is the number of resolvable (or modeled) paths from base station s to antenna a of the mobile, and is indexed from 1 to $L_{a,s}$;

$\alpha_{a,s,l}$ and $\tau_{a,s,l}$ are, respectively, the complex gain and delay associated with an l^{th} path from base station s to antenna a of the mobile;

K_s represents a number of active sub channels in base station s that employ code division multiplexing to share the channel. The sub channels are indexed from 1 to K_s ;

$u_{s,k}(t)$ is a code waveform (e.g., spreading waveform) used to carry a k^{th} sub channel's symbol for an s^{th} base station (e.g., a chip waveform modulated by a sub channel-specific Walsh code and covered with a base-station specific PN cover);

$b_{s,k}$ is a complex symbol being transmitted for the k^{th} sub channel of base station s; and

$w_a(t)$ denotes zero-mean complex additive noise on the a^{th} antenna. The term $w_a(t)$ may include thermal noise and any interference whose structure is not explicitly mod-

eled (e.g., inter-channel interference from unmodeled base stations, and/or intra-channel interference from unmodeled paths).

FIG. 1 illustrates an iterative interference suppressor in accordance with one embodiment of the invention. Received signals from each of a plurality of antennas **100.1-100.A** are processed by corresponding RAKE receivers **101.1-101.A**. Each RAKE receiver **101.1-101.A** may comprise a maximal ratio combiner (not shown).

Multi path components received by each RAKE receiver **101.1-101.A** are separated with respect to their originating base stations and processed by a plurality B of constituent-signal analyzers **102.1-102.B**. Each constituent-signal analyzer **102.1-102.B** comprises a combiner, a despreader, and a symbol estimator, such as combiner **111.s**, despreader **112.s**, and symbol estimator **113.s** in constituent-signal analyzer **102.s**.

Signals received from different antennas **100.1-100.A** corresponding to an s^{th} originating base station are synchronized, and then combined (e.g., maximal ratio combined) by combiner **111.s** to produce an s^{th} diversity-combined signal. The despreader **112.s** resolves the s^{th} diversity-combined signal onto sub channel code waveforms, and the symbol estimator **113.s** produces initial symbol estimates, which are input to a first interference suppression unit (ICU) **104.1** of a sequence of ICUs **104.1-104.M**.

ICU **104.1** mitigates intra-channel and/or inter-channel interference in the estimates in order to produce improved symbol estimates. Successive use of ICUs **104.2-104.M** further improves the symbol estimates. The ICUs **104.1-104.M** may comprise distinct units, or a single unit configured to perform each iteration.

FIG. 2 is a block diagram of a Rake receiver, such as RAKE receiver **101.a**. One of a plurality of processors **201.1-201.B** is associated with each base station. For example, processor **201.s** associated with an s^{th} base station comprises a plurality L of time-advance modules **202.1-202.L** configured to advance the received signal in accordance with L multi path time offsets. Weighting modules **203.1-203.L** provide corresponding maximal-ratio combining weights $\alpha_{a,s,l}$ to the time-advanced signals, and a combiner **204** combines the weighted signals to produce an output for the a^{th} antenna

$$y_{a,s}^{mrc}(t) = \frac{1}{\sqrt{E_s}} \sum_{l=1}^{L_{a,s}} \alpha_{a,s,l}^* y_a(t - \tau_{a,s,l}), \quad \text{Equation 2}$$

where $E_s = \sum_{l=1}^{L_{a,s}} |\alpha_{a,s,l}|^2$.

FIG. 3 is a block diagram of an exemplary constituent-signal analyzer, such as constituent-signal analyzer **102.s** shown in FIG. 1. A combiner **301** for a given base station sums the signals over the plurality A of antennas to produce a combined signal for base station s over all paths and all antennas

$$y_s^{mrc}(t) = \sum_{a=1}^A y_{a,s}^{mrc}(t). \quad \text{Equation 3}$$

The combined signal is resolved onto sub channel code waveforms by a plurality K of despreading modules, comprising K code-waveform multipliers **302.1-302.K** and integrators **303.1-303.K**, to give

$$q_{s,k} \equiv \frac{1}{E_s} \int_0^T u_{s,k}^*(t) y_s^{mrc}(t) dt \quad \text{Equation 4}$$

7

as a RAKE/Combine/De-Spread output for the k^{th} sub channel of base station s . A column vector of these outputs is denoted

$$\mathbf{q}_s = [q_{s,1} \ q_{s,2} \ \dots \ q_{s,K_s}]^T \quad \text{Equation 5}$$

for base station s , where the superscript T denotes matrix transpose. Each $q_{s,k}$ is processed by one of a plurality of symbol estimators **304.1-304.K** to produce

$$\hat{b}_{s,k}^{[0]} = \text{Estimate Symbol } \{q_{s,k}\}, \quad \text{Equation 6}$$

where the superscript [0] indicates the initial symbol estimate produced by front-end processing. Symbol estimators **304.1-304.K** may include mixed-decision symbol estimators described in U.S. Patent Application Ser. No. 60/736,204, or other types of symbol estimators. An output vector of symbol estimates for base station s may be formed as

$$\hat{\mathbf{b}}_s^{[0]} = [\hat{b}_{s,1}^{[0]} \ \hat{b}_{s,2}^{[0]} \ \dots \ \hat{b}_{s,K_s}^{[0]}]^T.$$

It should be appreciated that one or more of the functions described with respect to FIG. 3 may be implemented on discrete-time sequences generated by sampling (or filtering and sampling) continuous waveforms. More specifically, time advances (or delays) of waveforms become shifts by an integer number of samples in discrete-time sequences, and integration becomes summation.

FIG. 4 is a flow chart illustrating a functional embodiment of an ICU, such as one of the ICUs **104.1-104.M**. Similar ICU embodiments are described in U.S. Patent Application Ser. No. 60/736,204 for a system with a single receive antenna. However, the embodiment shown in FIG. 4 conditions a plurality of received antenna signals for a parallel bank of ICUs and conditions ICU outputs prior to making symbol estimates. Symbol estimates for a plurality of sources are input to the ICU and weighted **401.1-401.B** according to perceived merits of the symbol estimates. Any of the soft-weighting methods described in U.S. Patent Application Ser. No. 60/736,204 may be employed. The weighting of a k^{th} sub channel of base station s is expressed by

$$\gamma_{s,k}^{[i]} \hat{b}_{s,k}^{[i]} \quad \text{Equation 7}$$

where $\hat{b}_{s,k}^{[i]}$ is the input symbol estimate, $\gamma_{s,k}^{[i]}$ is its weighting factor, and superscript [i] represents the output of the i^{th} ICU. The superscript [0] represents the output of front-end processing prior to the first ICU. The symbol estimates may be multiplexed (e.g., concatenated) **402** into a single column vector

$$\hat{\mathbf{b}}^{[i]} = [(\hat{b}_1^{[i]})^T (\hat{b}_2^{[i]})^T \ \dots \ (\hat{b}_B^{[i]})^T]^T$$

such that the weighted symbol estimates are given by $\Gamma^{[i]} \hat{\mathbf{b}}^{[i]}$, where $\Gamma^{[i]}$ is a diagonal matrix containing the weighting factors along its main diagonal. The weighted symbol estimates are processed by a synthesizer used to synthesize **403.1-403.A** constituent signals for each antenna. For each antenna, a synthesized signal represents a noise-free signal that would have been observed at antennas a with the base stations transmitting the weighted symbol estimates $\Gamma^{[i]} \hat{\mathbf{b}}^{[i]}$ over the multi path channels between base stations 1 through B and the mobile receiver.

For each antenna, a subtraction module performs interference suppression **404.1-404.A** on the constituent signals to reduce the amount of intra-channel and inter-channel interference. The interference-suppressed constituents are processed via per-antenna RAKE processing and combining **405.1-405.A** to produce combined signals. The combined signals are organized by base station, combined across antennas, resolved onto the sub channel code waveforms, and processed by symbol estimators **406.1-406.B**. The terms $\hat{b}_{s,k}$

8

$^{[i+1]}$ denote the estimated symbol for the k^{th} sub channel of base station s after processing by the $(i+1)^{th}$ ICU.

FIG. 5a illustrates an apparatus configured for generating multi path finger constituent signals and FIG. 5b shows an apparatus configured for generating sub channel constituents. A plurality of processors **501.1-501.B** is configured for processing signals received from each base station. For an s^{th} base station, a plurality K_s of multipliers **502.1-502.K** scales each code waveform with a corresponding weighted symbol estimate to produce a plurality of estimated transmit signals, which are combined by combiner **503** to produce a superposition signal

$$\sum_{k=0}^{K_s-1} \gamma_{s,k}^{[i]} \hat{b}_{s,k}^{[i]} u_{s,k}(t) \quad \text{Equation 8}$$

A multi path channel emulator comprising path-delay modules **504.1-504.L** and path-gain modules **505.1-505.L** produces multi path finger constituent signals expressed by

$$\tilde{y}_{a,s,l}^{[i]}(t) = \alpha_{a,s,l} \sum_{k=0}^{K_s-1} \gamma_{s,k}^{[i]} \hat{b}_{s,k}^{[i]} u_{s,k}(t - \tau_{a,s,l}), \quad \text{Equation 9}$$

where $\tilde{y}_{a,s,l}^{[i]}(t)$ is the l^{th} finger constituent for the channel between base station s and antenna a .

FIG. 5b shows an apparatus configured for generating sub channel constituents. For a particular antenna a , a processor **510.1-510.B** is configured for processing signals received from each base station. Within each base station processor **510.1-510.B**, a plurality of processors **511.1-511.K** are configured for processing each sub channel. Each sub channel processor **511.1-511.K** comprises a multiplier **512** that scales a k^{th} code waveform with a corresponding weighted symbol estimate to produce an estimated transmit signal, which is processed by a multi path channel emulator comprising path delay modules **513.1-513.L**, path-gain modules **514.1-514.L**, and a combiner of the multiple paths **515** to produce

$$\tilde{y}_{a,s,l}^{[i]}(t) = \gamma_{s,k}^{[i]} \hat{b}_{s,k}^{[i]} \sum_{l=0}^{L_{a,s}} \alpha_{a,s,l} u_{s,k}(t - \tau_{a,s,l}), \quad \text{Equation 10}$$

which is the synthesized constituent signal for the k^{th} sub channel of base station s at the a^{th} antenna of the mobile. Note that while Equation 9 and Equation 10 both show a signal with a three-parameter subscript for their left-hand sides, they are different signals; the subscript l (as in Equation 9) will be reserved for a finger constituent and the subscript k (as in Equation 10) will be reserved for a sub channel constituent.

FIG. 6 is a block diagram showing an apparatus configured for performing interference suppression on synthesized constituent signals for each antenna. Since, the constituent signals for each antenna a may comprise multi path finger constituents or sub channel constituents. The index $j \in \{1, \dots, J_{a,s}\}$ is introduced, where

$$J_{a,s} = \begin{cases} L_{a,s} & \text{for finger constituents} \\ K_s & \text{for subchannel constituents} \end{cases}$$

A first processor **600** comprises a plurality B of subtractive suppressors **601.1-601.B** configured for processing constituent signals relative to each of a plurality B of base stations.

Suppressor **601.s** is illustrated with details that may be common to the other suppressors **601.1-601.B**. A combiner **602** sums the constituent signals to produce a synthesized received signal associated with base station s , $\tilde{y}_{a,s}^{[i]}(t) = \sum_{j=0}^{J_{a,s}} \tilde{y}_{a,s,j}^{[i]}(t)$, where $\tilde{y}_{a,s,j}^{[i]}$ is the j^{th} constituent finger or sub channel signal on the a^{th} antenna for base station s .

A second processor **610** comprises a combiner **611** configured for combining the synthesized received signals across base stations to produce a combined synthesized receive signal $\tilde{y}_a^{[i]}(t) = \sum_{s=1}^B \tilde{y}_{a,s}^{[i]}$ corresponding to the a^{th} antenna. A

subtraction module **612** produces a signal from the difference between the combined synthesized receive signal and the actual received signal to create a residual signal $y_a(t) - \tilde{y}_a^{[i]}(t)$. A step size scaling module **613** scales the residual signal with a complex stabilizing step size $\mu_a^{[i]}$ **613** to give a scaled residual signal $\mu_a^{[i]}(y_a(t) - \tilde{y}_a^{[i]}(t))$. The scaled residual signal is returned to the suppressors **601.I-601.B** in the first processor **601** where combiners, such as combiners **603.1-603.J** in the suppressor **601.s** add the scaled residual signal to the constituent signals to produce a set of interference-suppressed constituents expressed by

$$z_{a,s,j}^{[i]}(t) = \tilde{y}_{a,s,j}^{[i]}(t) + \mu_a^{[i]}(y_a(t) - \tilde{y}_a^{[i]}(t)) \quad \text{Equation 11}$$

for an interference-suppressed j^{th} constituent finger or sub channel signal on the a^{th} antenna for base station s . The term $\mu_a^{[i]}$ may be evaluated as shown in U.S. patent application Ser. No. 11/451,932, which describes calculating a step size for a single receive antenna. In one embodiment the same step size may be employed for all antennas, meaning $\mu_a^{[i]} = \mu^{[i]}$ for all a .

FIG. 7a is a block diagram of an apparatus configured for performing RAKE processing and combining **405.1-405.A** on the interference-suppressed constituent signals for each antenna. Each of a plurality B of Rake processors **701.1-701.B** is configured for processing finger constituents for each base station. Processor **701.s** shows components that are common to all of the processors **701.1-701.B**. A plurality L of time-advance modules **702.1-702.L** advance finger signal inputs by multi path time shifts. Scaling modules **703.1-703.L** scale the time-shifted inputs by complex channel gains, and the resulting scaled signals are summed **704** to yield the maximal ratio combined (MRC) output

$$z_{a,s}^{mrc,[i]}(t) = \frac{1}{\sqrt{E_s}} \sum_{l=1}^{L_{a,s}} \alpha_{a,s,l}^* z_{a,s,l}(t - \tau_{a,s,l}) \quad \text{Equation 12}$$

associated with antenna a and base station s ,

In FIG. 7b, Rake processors **710.1-710.B** may each comprise a combiner **711** configured for summing the sub channel constituent signals, a plurality L of time-advance modules **712.1-712.L** configured for advancing the sum by multi path time offsets, scaling modules **713.1-713.L** configured for scaling the sum by corresponding multi path channel gains, and a combiner **714** configured for summing the scaled signals to produce the MRC output

$$z_{a,s}^{mrc,[i]}(t) = \frac{1}{\sqrt{E_s}} \sum_{l=1}^{L_{a,s}} \alpha_{a,s,l}^* \sum_{k=1}^{K_s} z_{a,s,k}(t - \tau_{a,s,l}) \quad \text{Equation 13}$$

associated with antenna a and base station s .

FIG. 8 shows an apparatus configured for performing the steps **406.1-406.B** shown in FIG. 4 to produce the updated symbol estimates. Each of a plurality B of processors **801.1-801.B** is configured for processing the MRC outputs. Processor **801.s** shows details that are common to all of the processors **801.1-801.B**.

For each base station, the MRC signals for all antennas are summed **802** to form the overall MRC signal

$$z_s^{mrc,[i]}(t) = \sum_{a=1}^A z_{a,s}^{mrc,[i]}(t), \quad \text{Equation 14}$$

which is resolved by code multipliers **803.1-803.K** and integrators **804.1-804.K** onto the sub channel code waveforms. Symbol estimators **805.1-805.K** are employed for producing symbol estimates, such as mixed-decision symbol estimates as described in U.S. patent application Ser. No. 11/451,932.

Because of the linear nature of many of the ICU components, alternative embodiments of the invention may comprise similar components employed in a different order of operation without affecting the overall functionality. In one embodiment, antenna combining and de-spreading may be performed prior to interference suppression, such as illustrated in FIG. 9.

FIG. 9a illustrates a plurality of processing blocks **901.1-901.B** configured for processing constituent finger or sub-channel signals received from each of a plurality of base stations. The constituent signals are subtracted from the received signal on antenna a by a subtraction module **902** to produce a residual signal. The residual signal is processed by a RAKE **903.1-903.L** and maximal ratio combiner (comprising weighting modules **904.1-904.L** and an adder **905**) to produce an error signal $e_{a,s}^{[i]}(t)$ for antenna a and base station s .

In FIG. 9b, each of a plurality of processing blocks **911.1-911.B** is configured to combine the error signals produced by the apparatus shown in FIG. 9a. In processing block **911.s**, a combiner **912** combines the error signals corresponding to the s^{th} base station across the antennas to produce $e_s^{[i]}(t)$, the error signal for base station s . Despanders comprising code multipliers **913.1-913.K** and integrators **914.1-914.K** resolve the error signal $e_s^{[i]}(t)$ onto code waveforms of sub channels associated with the s^{th} base station.

The output for the k^{th} sub channel of base station s is $\int_0^T u_k^*(t) e_s^{[i]}(t) dt$, which is equal to $q_{s,k} - \tilde{q}_{s,k}^{[i]}$, where $q_{s,k}$ is defined in Equation 4, and

$$\tilde{q}_{s,k}^{[i]} = \frac{1}{E_s} \sum_{a=1}^A \int_0^T u_k^*(t) \sum_{l=1}^{L_{a,s}} \alpha_{a,s,l}^* \tilde{y}_{a,s,j}(t - \tau_{a,s,l}) dt$$

For each base station, the values $q_{s,k}$ and $\tilde{q}_{s,k}^{[i]}$ may be stacked into a vector over the sub channel index k to form $q_s - \tilde{q}_s^{[i]}$. These likewise may be stacked into a single vector over the base station index s to give $q - \tilde{q}^{[i]}$. This quantity may also be determined explicitly using a matrix multiplication.

FIG. 9c illustrates a final step of an interference-suppression process. A stabilizing step size module **921** scales the difference $q - \tilde{q}^{[i]}$ by a stabilizing step size $\mu^{[i]}$, and the result is added **923** to the weighted input vector $\Gamma^{[i]} \hat{b}^{[i]}$ after being multiplied **922** by implementation matrix F to produce a vector sum. The value of the implementation matrix F depends on whether finger or sub channel constituents are used. A symbol estimator **924** produces symbol estimates for each element of the vector sum.

An explicit implementation of an ICU is illustrated in FIG. 10. The input symbol estimates are weighted **1000** and multiplied by a matrix R **1001**. The resulting product is subtracted **1002** from front-end vector q and scaled with the stabilizing step size $\mu^{[i]}$ by a stabilizing step size module **1003**. The resulting scaled signal is summed **1004** with weighted symbol estimates multiplied **1005** by the implementation matrix F to produce a vector sum. A symbol estimator **1006** makes decisions on the vector sum.

Matrix R is the correlation matrix for all sub channels at the receiver after combining across antennas. It may be evaluated by

$$R = \sum_{a=1}^A R_a \quad \text{Equation 15}$$

where R_a is the correlation matrix for all sub channels at the a^{th} antenna, and it may be determined as described in U.S. patent application Ser. No. 11/451,932 for a single antenna

11

receiver. The matrix F is either the identity matrix when sub channel constituent signals are employed or the correlation matrix for all sub channels at the transmitter(s) when finger constituent signals are used, such as described in U.S. patent application Ser. No. 11/451,932. This functionality may be represented by the one-step matrix-update equation

$$\hat{\mathbf{b}}^{[i+1]} = \Psi(\mu^{[i]}(\mathbf{q} - \mathbf{R}\Gamma^{[i]}\hat{\mathbf{b}}^{[i]}) + \mathbf{F}\Gamma^{[i]}\hat{\mathbf{b}}^{[i]}), \quad \text{Equation 16}$$

where $\Psi(\cdot)$ represents any function that returns a symbol estimate for each element of its argument (including, for example, any of the mixed-decision symbol estimation functions described in U.S. patent application Ser. No. 11/451,932) and all other quantities as previously described.

The stabilizing step size $\mu^{[i]}$ may take any of the forms described in U.S. patent application Ser. No. 11/451,932 that depend on the correlation matrix R, the implementation matrix F, and the weighting matrix $\Gamma^{[i]}$. Two of these forms of $\mu^{[i]}$ are implicitly calculable, such as described in U.S. patent application Ser. No. 11/451,932 for a single receive antenna.

FIG. 11a illustrates a method for calculating a stabilizing step size when multiple receive antennas are employed. Preliminary processing **1101.1-1101.A** for each antenna provides for RAKE processing, combining, and de-spreading **1102** on the received signal, and RAKE processing, combining, and de-spreading **1103** on the synthesized received signal and produces **1113** a difference signal. In an alternative embodiment for the preliminary processing **1101.1-1101.A** shown in FIG. 11b, a difference signal calculated from the received signal and the synthesized received signal undergoes RAKE processing, combining, and de-spreading **1110.a**.

The difference-signal vector corresponding to the a^{th} antenna is denoted by $\underline{\beta}_a^{[i]}$. The difference-signal vectors for all of the antennas are summed to produce a sum vector $\underline{\beta}^{[i]}$. A sum of the square magnitudes **1105** of the elements of the sum vector (i.e., $\|\underline{\beta}^{[i]}\|^2$) provides a numerator of a ratio from which the stabilizing step size is evaluated. The elements of $\underline{\beta}^{[i]}$ are used as transmit symbols in order to synthesize **1106** received signals for each antenna. Synthesized received signals are expressed as

$$\sum_{s=1}^B \sum_{l=1}^{L_{G,S}} \alpha_{a,s,l}^* \sum_{k=1}^{K_s} \beta_{s,k}^{[i]} u_{s,k}(t - \tau_{a,s,l})$$

for antenna a, where $\beta_{s,k}^{[i]}$ is the k^{th} element of $\underline{\beta}^{[i]}$. An integral of the square magnitude of each synthesized signal is calculated **1108.1-1108.A** and summed **1109** to produce the denominator of the ratio. The ratio of the numerator and the denominator gives the first version of the step size $\mu^{[i]}$.

FIG. 11c shows an implicit evaluation of the step size in accordance with another embodiment of the invention. The denominator of the ratio used to calculate the stabilizing step size is determined by weighting **1150** the vector $\underline{\beta}^{[i]}$ by soft weights (such as contained in the diagonal matrix $\Gamma^{[i]}$). The elements of the resulting weighted vector are used to produce **1151** synthesized received signals for all of the antennas. Integrals of the square magnitudes of the synthesized received signals are calculated **1152.1-1152.A** and summed **1153** to provide the denominator.

The corresponding numerator is calculated by scaling **1154** symbol estimates produced at the i^{th} iteration by the square of the soft weights (as contained in the diagonal matrix $(\Gamma^{[i]})^2$). The resulting scaled vector is used to synthesize **1155** received signals for all of the antennas. The synthesized signals and the received signals are processed by a parallel bank

12

of processors **1156.1-1156.A**, each corresponding to a particular antenna. The functionality of each processor **1156.1-1156.A** may be equivalent to the processor **1101.a** shown in FIG. 11a. The vector outputs of the processors **1156.1-1156.A** are summed **1157**, and the numerator is produced from the inner product **1158** of the sum vector with the weighted vector.

Explicit versions of both versions of the step size are given, respectively, by

$$\mu^{[i]} = \frac{(\mathbf{q} - \mathbf{R}\mathbf{F}\Gamma^{[i]}\hat{\mathbf{b}}^{[i]})^H (\mathbf{q} - \mathbf{R}\mathbf{F}\Gamma^{[i]}\hat{\mathbf{b}}^{[i]})}{(\mathbf{q} - \mathbf{R}\Gamma^{[i]}\hat{\mathbf{b}}^{[i]})^H \mathbf{R}(\mathbf{q} - \mathbf{R}\Gamma^{[i]}\hat{\mathbf{b}}^{[i]})} \quad \text{Equation 17}$$

and

$$\mu^{[i]} = \frac{(\mathbf{q} - \mathbf{R}\Gamma^{[i]}\mathbf{F}\Gamma^{[i]}\hat{\mathbf{b}}^{[i]})^H \Gamma^{[i]}(\mathbf{q} - \mathbf{R}\Gamma^{[i]}\hat{\mathbf{b}}^{[i]})}{(\mathbf{q} - \mathbf{R}\Gamma^{[i]}\hat{\mathbf{b}}^{[i]})^H (\Gamma^{[i]})^H \mathbf{R}\Gamma^{[i]}(\mathbf{q} - \mathbf{R}\Gamma^{[i]}\hat{\mathbf{b}}^{[i]})} \quad \text{Equation 18}$$

wherein all quantities shown are as previously defined.

Another form of the step size in U.S. patent application Ser. No. 11/451,932 depends only on the path gains, and may be generalized to multiple receive antennas according to

$$\mu^{[i]} = \mu = \max \left\{ C, \frac{\max_{a,l} \sum_{s=1}^A |\alpha_{a,s,l}|^p}{\sum_{a=1}^A \sum_{s=1}^B \sum_{l=1}^{L_{G,S}} |\alpha_{a,s,l}|^p} \right\}, \quad \text{Equation 19}$$

where $\mu^{[i]}$ is fixed for every ICU and C and p are non-negative constants.

Embodiments of the invention are also applicable to the reverse-link, such as described for the single receive antenna in U.S. patent application Ser. No. 11/451,932. The primary difference (when compared to the forward-link) is that sub channels from distinct transmitters experience different multi path channels and, thus, the receiver must accommodate each sub channel with its own RAKE/Combiner/De-Spreader, and channel emulation must take into account that, in general, every sub channel sees its own channel. Such modifications are apparent to those knowledgeable in the art.

Embodiments of the invention may be realized in hardware or software and there are several modifications that can be made to the order of operations and structural flow of the processing. Those skilled in the art should recognize that method and apparatus embodiments described herein may be implemented in a variety of ways, including implementations in hardware, software, firmware, or various combinations thereof. Examples of such hardware may include Application Specific Integrated Circuits (ASICs), Field Programmable Gate Arrays (FPGAs), general-purpose processors, Digital Signal Processors (DSPs), and/or other circuitry. Software and/or firmware implementations of the invention may be implemented via any combination of programming languages, including Java, C, C++, Matlab™, Verilog, VHDL, and/or processor specific machine and assembly languages.

Computer programs (i.e., software and/or firmware) implementing the method of this invention may be distributed to users on a distribution medium such as a SIM card, a USB memory interface, or other computer-readable memory adapted for interfacing with a consumer wireless terminal. Similarly, computer programs may be distributed to users via wired or wireless network interfaces. From there, they will often be copied to a hard disk or a similar intermediate storage

13

medium. When the programs are to be run, they may be loaded either from their distribution medium or their intermediate storage medium into the execution memory of a wireless terminal, configuring an onboard digital computer system (e.g., a microprocessor) to act in accordance with the method of this invention. All these operations are well known to those skilled in the art of computer systems.

The functions of the various elements shown in the drawings, including functional blocks labeled as “modules” may be provided through the use of dedicated hardware, as well as hardware capable of executing software in association with appropriate software. When provided by a processor, the functions may be performed by a single dedicated processor, by a shared processor, or by a plurality of individual processors, some of which may be shared. Moreover, explicit use of the term “processor” or “module” should not be construed to refer exclusively to hardware capable of executing software, and may implicitly include, without limitation, digital signal processor DSP hardware, read-only memory (ROM) for storing software, random access memory (RAM), and non-volatile storage. Other hardware, conventional and/or custom, may also be included. Similarly, the function of any component or device described herein may be carried out through the operation of program logic, through dedicated logic, through the interaction of program control and dedicated logic, or even manually, the particular technique being selectable by the implementer as more specifically understood from the context.

The method and system embodiments described herein merely illustrate particular embodiments of the invention. It should be appreciated that those skilled in the art will be able to devise various arrangements, which, although not explicitly described or shown herein, embody the principles of the invention and are included within its spirit and scope. Furthermore, all examples and conditional language recited herein are intended to be only for pedagogical purposes to aid the reader in understanding the principles of the invention. This disclosure and its associated references are to be construed as applying without limitation to such specifically recited examples and conditions. Moreover, all statements herein reciting principles, aspects, and embodiments of the invention, as well as specific examples thereof, are intended to encompass both structural and functional equivalents thereof. Additionally, it is intended that such equivalents include both currently known equivalents as well as equivalents developed in the future, i.e., any elements developed that perform the same function, regardless of structure.

We claim:

1. A wireless terminal, comprising:

- a plurality of antennas configured to receive multiple-access communication signals from a plurality of transmission sources;
- a plurality of RAKE receivers configured to separate the multiple-access communication signals into a plurality of constituent signals for each transmission source;
- a plurality of constituent-signal analyzers configured to generate a plurality of initial symbol estimates from the plurality of constituent signals; and
- one or more interference suppression units configured to generate, from the plurality of initial symbol estimates, a synthesized received signal for each antenna of the plurality of antenna, subtract the respective synthesized received signal from the multiple-access communication signal received by each antenna to obtain a plurality of residual signals for the plurality of antenna, combine the plurality of residual signals with the plurality of constituent signals to obtain interference-suppressed

14

constituent signals, and generate a plurality of updated symbol estimates based on the interference-suppressed constituent signals.

2. The wireless terminal of claim 1, wherein an interference suppression unit of the one or more interference suppression units is configured to generate, from the plurality of initial symbol estimates, multipath constituent signals for each transmission source of the plurality of transmission sources relative to an antenna of the plurality of antennas, and generate, for the antenna, a residual signal of the plurality of residual signals based on the multipath constituent signals.

3. The wireless terminal of claim 1, wherein an interference suppression unit of the one or more interference suppression units, comprises:

- a multipath constituent generator configured to generate, from the plurality of initial symbol estimates, multipath constituent signals for each transmission source of the plurality of transmission sources relative to an antenna of the plurality of antennas;

- a plurality of subtractive suppressors, each configured to combine the multipath constituent signals for a respective transmission source to obtain a combined multipath signal for the respective transmission source, and combine a residual signal of the plurality of residual signals with the multipath constituent signals for the respective transmission source to obtain the interference-suppressed constituent signals; and

- a processor configured to combine the combined multipath signals for the plurality of transmission sources relative to the antenna of the plurality of antennas to obtain the synthesized received signal for the antenna, and subtract the synthesized received signal from the multiple-access communication signal received by the antenna to obtain the residual signal.

4. The wireless terminal of claim 1, wherein an interference suppression unit of the one or more interference suppression units, comprises:

- a multipath constituent generator configured to generate, from the plurality of initial symbol estimates, multipath constituent signals for each transmission source of the plurality of transmission sources relative to an antenna of the plurality of antennas;

- a plurality of subtractive suppressors, each configured to combine the multipath constituent signals for a respective transmission source to obtain a combined multipath signal for the respective transmission source, and combine a scaled residual signal with the multipath constituent signals for the respective transmission source to obtain the interference-suppressed constituent signals; and

- a processor configured to combine the combined multipath signals for the plurality of transmission sources relative to the antenna of the plurality of antennas to obtain the synthesized received signal for the antenna, subtract the synthesized received signal from the multiple-access communication signal received by the antenna to obtain a residual signal of the plurality of residual signals, and scale the residual signal by a stabilizing step size to obtain the scaled residual signal.

5. The wireless terminal of claim 1, wherein an interference suppression unit of the one or more interference suppression units, is configured to generate, from the plurality of initial symbol estimates, subchannel constituent signals for each transmission source of the plurality of transmission sources relative to an antenna of the plurality of antennas, and generate the plurality of residual signals based on the subchannel constituent signals.

15

6. The wireless terminal of claim 1, wherein an interference suppression unit of the one or more interference suppression units, comprises:

- a subchannel constituent generator configured to generate, from the plurality of initial symbol estimates, subchannel constituent signals for each transmission source of the plurality of transmission sources relative to an antenna of the plurality of antennas;
- a plurality of subtractive suppressors, each configured to combine the subchannel constituent signals for a respective transmission source to obtain a combined subchannel signal for the respective transmission source, and combine a residual signal of the plurality of residual signals with the subchannel constituent signals for the respective transmission source to obtain the interference-suppressed constituent signals; and
- a processor configured to combine the combined subchannel signals for the plurality of transmission sources relative to the antenna of the plurality of antennas to obtain the synthesized received signal for the antenna, and subtract the synthesized received signal from the multiple-access communication signal received by the antenna to obtain the residual signal.

7. The wireless terminal of claim 1, wherein an interference suppression unit of the one or more interference suppression units, comprises:

- a subchannel constituent generator configured to generate, from the plurality of initial symbol estimates, subchannel constituent signals for each transmission source of the plurality of transmission sources relative to an antenna of the plurality of antennas;
- a plurality of subtractive suppressors, each configured to combine the subchannel constituent signals for a respective transmission source to obtain a combined subchannel signal for the respective transmission source, and combine a scaled residual signal with the subchannel constituent signals for the respective transmission source to obtain the interference-suppressed constituent signals; and
- a processor configured to combine the combined subchannel signals for the plurality of transmission sources relative to the antenna of the plurality of antennas to obtain the synthesized received signal for the antenna, subtract the synthesized received signal from the multiple-access communication signal received by the antenna to obtain a residual signal of the plurality of residual signals, and scale the residual signal by a stabilizing step size to obtain the scaled residual signal.

8. The wireless terminal of claim 1, wherein:

- the one or more interference suppression units comprise at least a first interference suppression unit and a second interference suppression unit;
- the first interference suppression unit is configured to receive the plurality of initial symbol estimates and generate a first plurality of updated symbol estimates; and
- the second interference suppression unit is configured to receive the first plurality of updated symbol estimates from the first interference suppression unit as its plurality of initial symbol estimates and generate a second plurality of updated symbol estimates.

9. The wireless terminal of claim 1, wherein the one or more interference suppression units consists of a single interference suppression configured to iteratively update the plurality of initial symbol estimates to obtain the plurality of updated symbol estimates.

16

10. A wireless terminal, comprising:

- a plurality of antennas configured to receive multiple-access communication signals from a plurality of transmission sources;
- a plurality of RAKE receivers configured to separate the multiple-access communication signals into a plurality of constituent signals for each transmission source;
- a computer-readable memory with stored firmware; and
- a processor configured to execute the stored firmware of the computer-readable memory, wherein the processor, in response to executing the stored firmware, is configured to:
 - generate a plurality of initial symbol estimates from the plurality of constituent signals;
 - generate, from the plurality of initial symbol estimates, a synthesized received signal for each antenna of the plurality of antenna;
 - subtract the respective synthesized received signal from the multiple-access communication signal received by each antenna to obtain a plurality of residual signals for the plurality of antenna;
 - combine the plurality of residual signals with the plurality of constituent signals to obtain interference-suppressed constituent signals; and
 - generate a plurality of updated symbol estimates based on the interference-suppressed constituent signals.

11. The wireless terminal of claim 10, wherein the processor, in response to executing the stored firmware, is further configured to:

- generate, from the plurality of initial symbol estimates, multipath constituent signals for each transmission source of the plurality of transmission sources relative to an antenna of the plurality of antennas; and
- generate, for the antenna, a residual signal of the plurality of residual signals based on the multipath constituent signals.

12. The wireless terminal of claim 10, wherein the processor, in response to executing the stored firmware, is further configured to:

- generate, from the plurality of initial symbol estimates, multipath constituent signals for each transmission source of the plurality of transmission sources relative to an antenna of the plurality of antennas;
- combine the multipath constituent signals for a respective transmission source to obtain a combined multipath signal for the respective transmission source;
- combine a residual signal of the plurality of residual signals with the multipath constituent signals for the respective transmission source to obtain the interference-suppressed constituent signals;
- combine the combined multipath signals for the plurality of transmission sources relative to the antenna of the plurality of antennas to obtain the synthesized received signal for the antenna; and
- subtract the synthesized received signal from the multiple-access communication signal received by the antenna to obtain the residual signal.

13. The wireless terminal of claim 10, wherein the processor, in response to executing the stored firmware, is further configured to:

- generate, from the plurality of initial symbol estimates, multipath constituent signals for each transmission source of the plurality of transmission sources relative to an antenna of the plurality of antennas;
- combine the multipath constituent signals for a respective transmission source to obtain a combined multipath signal for the respective transmission source;

17

combine a scaled residual signal with the multipath constituent signals for the respective transmission source to obtain the interference-suppressed constituent signals; combine the combined multipath signals for the plurality of transmission sources relative to the antenna of the plurality of antennas to obtain the synthesized received signal for the antenna;

subtract the synthesized receive signal from the multiple-access communication signal received by the antenna to obtain a residual signal of the plurality of residual signals; and

scale the residual signal by a stabilizing step size to obtain the scaled residual signal.

14. The wireless terminal of claim **10**, wherein the processor, in response to executing the stored firmware, is further configured to:

generate, from the plurality of initial symbol estimates, subchannel constituent signals for each transmission source of the plurality of transmission sources relative to an antenna of the plurality of antennas; and

generate the plurality of residual signals based on the subchannel constituent signals.

15. The wireless terminal of claim **10**, wherein the processor, in response to executing the stored firmware, is further configured to:

generate, from the plurality of initial symbol estimates, subchannel constituent signals for each transmission source of the plurality of transmission sources relative to an antenna of the plurality of antennas;

combine the subchannel constituent signals for a respective transmission source to obtain a combined subchannel signal for the respective transmission source;

combine a residual signal of the plurality of residual signals with the subchannel constituent signals for the respective transmission source to obtain the interference-suppressed constituent signals;

18

combine the combined subchannel signals for the plurality of transmission sources relative to the antenna of the plurality of antennas to obtain the synthesized received signal for the antenna; and

subtract the synthesized receive signal from the multiple-access communication signal received by the antenna to obtain the residual signal.

16. The wireless terminal of claim **10**, wherein the processor, in response to executing the stored firmware, is further configured to:

generate, from the plurality of initial symbol estimates, subchannel constituent signals for each transmission source of the plurality of transmission sources relative to an antenna of the plurality of antennas;

combine the subchannel constituent signals for a respective transmission source to obtain a combined subchannel signal for the respective transmission source;

combine a scaled residual signal with the subchannel constituent signals for the respective transmission source to obtain the interference-suppressed constituent signals;

combine the combined subchannel signals for the plurality of transmission sources relative to the antenna of the plurality of antennas to obtain the synthesized received signal for the antenna;

subtract the synthesized received signal from the multiple-access communication signal received by the antenna to obtain a residual signal of the plurality of residual signals; and

scale the residual signal by a stabilizing step size to obtain the scaled residual signal.

17. The wireless terminal of claim **10**, wherein the processor, in response to executing the stored firmware, is further configured to iteratively update the plurality of initial symbol estimates to obtain the plurality of updated symbol estimates.
